Increasing evidence links antibiotic consumption with bone mineralization and fracture risk. However, it is not clear if this is explained by the antimicrobial activity or by unspecific pharmacological effects. Consequently, it is not known if the risk of osteoporotic fracture and/or other adverse outcomes is reduced by antibiotic treatment. The current review summarizes the evidence on the bone-protective effects of antimicrobials, with special emphasis on effects beyond the antimicrobial activity. A literature search in PubMed and ISI Web of Knowledge was performed to find original articles, case-control and cohort studies on the relationship between exposure to specific antimicrobials and the risk of hip and/or osteoporotic fracture. Four major conclusions are drawn: (1) antimicrobials do not have a clear bone-protective effect, i.e. exposure in childhood or at later ages seems not to be associated with later reduced bone mineralization; (2) penicillin is not consistently associated with reduced bone mineralization; (3) in women, the risk of hip fracture is increased by antimicrobial treatment; and (4) exposure to trimethoprim/sulfonamides and trimethoprim/macrolide seems to be associated with increased risk of hip fracture. The effect of antibiotics on bone health is not entirely explained by their effects on bacterial infections. The pattern of an increased risk of hip fracture in women but not men, and of reduced bone mineral density by penicillin but not other antimicrobials, indicates that unspecific pharmacological effects may contribute. There is good evidence that, on the other hand, the use of trimethoprim/sulfonamides and trimethoprim/macrolide increases the risk of hip fractures. The data on the bone-protective effects of newer and more specific antimicrobials are limited.Q: Is there a way to reset the auto-login functionality in the new admin pages? In Drupal 7, the "admin pages" used to be accessed from a file located in /admin/people. This file has been replaced by a new admin
